Portfolio Project: Report Back

The main difference between React and Bootstrap is the language they're based on. React is based on vanilla javascript whereas Bootstrap is based on css. For example, Bootstrap focuses more on UI responsiveness and quick styling. Where on the other hand, React focuses on functions, structure, components, setting state(if needed) and compiling your project. You'll be able to directly insert data and map it across your site using javascript functions like map().

In the case of my personal project, I will have to create custom components like post, user, form, navbar, footer, etc. The navbar and footer like components will be created for the purpose of splitting up the code to make it more readable and manageable. While components like post will consume an array of data and create a new post element for each set.
